

PROJECT PRODUCTION  
INSTITUTE

# Operations Management Framework for Project Production System Design

Mark Spearman & James Choo

2015 Symposium  
San Francisco | 9 December 2015

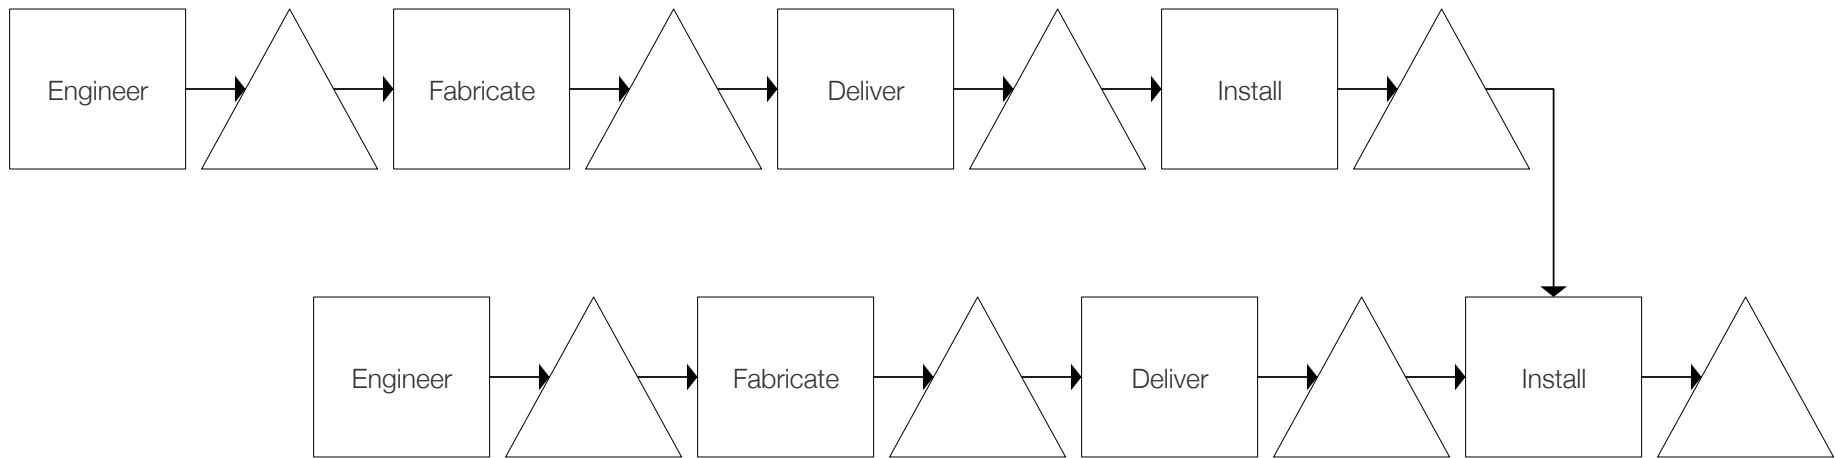

## Supply Flow

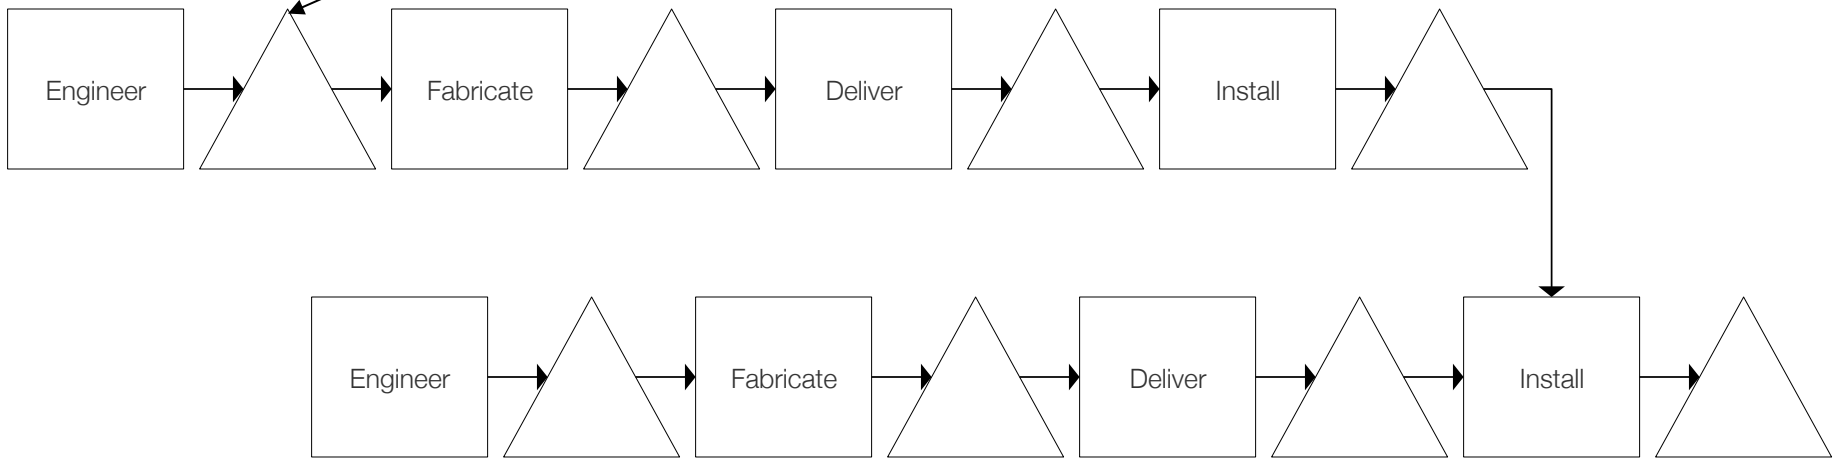

*Site Assembly Process*

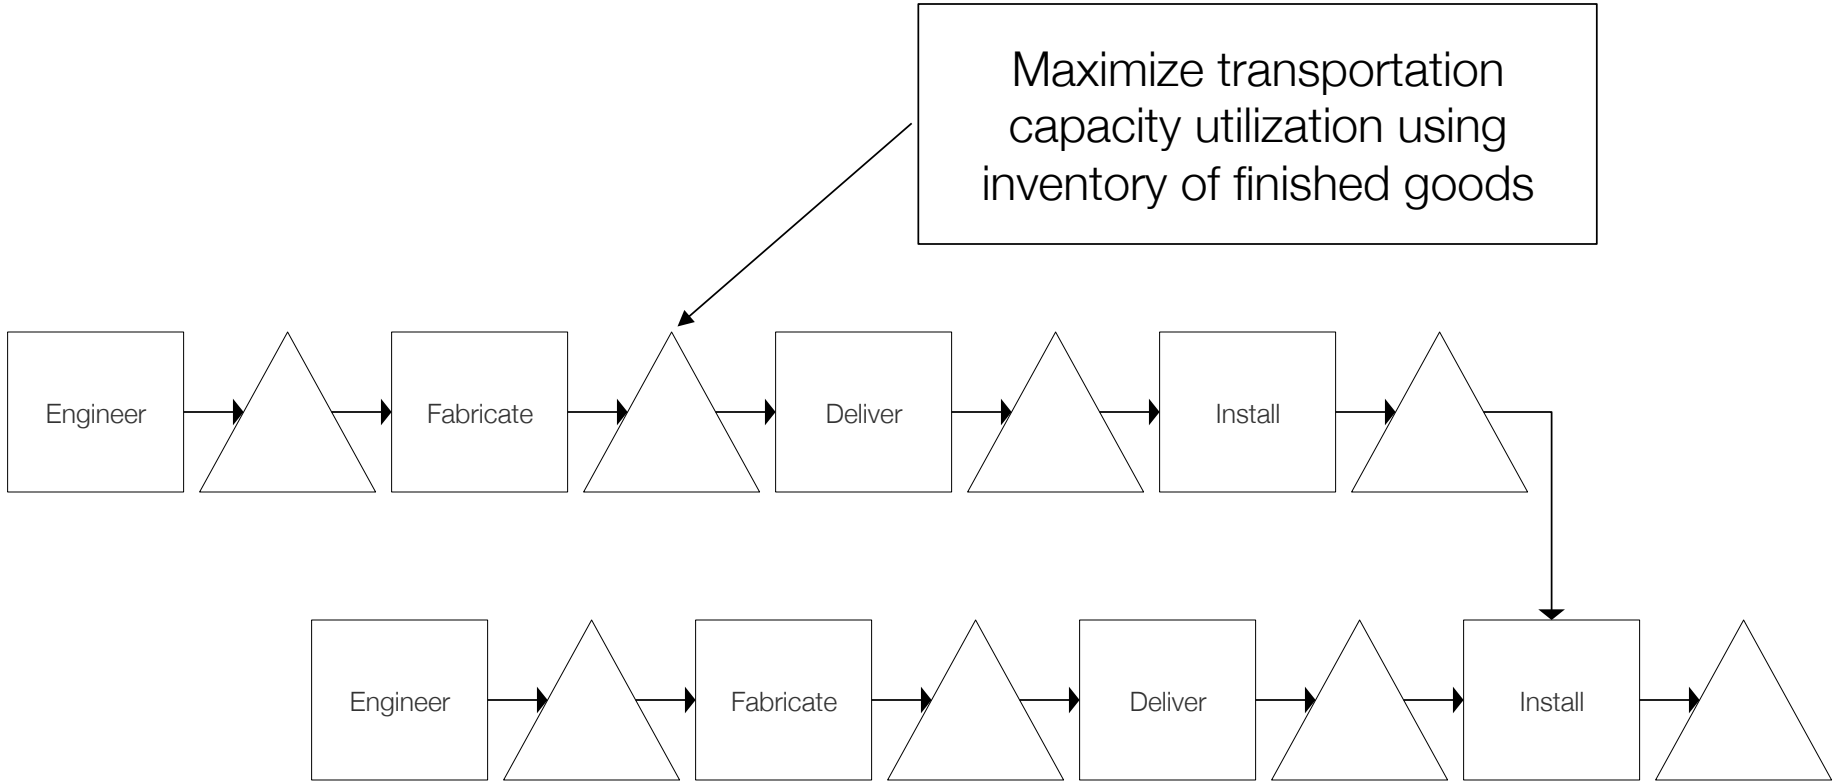

# Project as a Flow

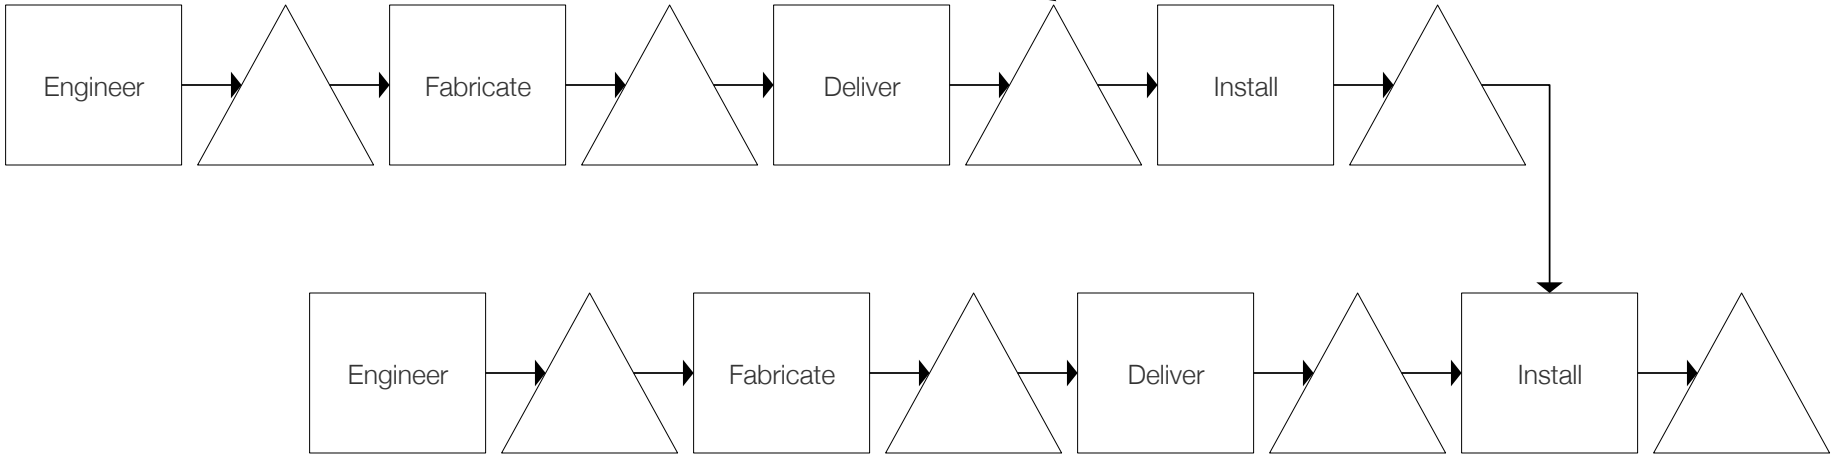

Maximize fabrication capacity utilization & minimize material waste using design/engineering inventory

Maximize transportation capacity utilization using inventory of finished goods

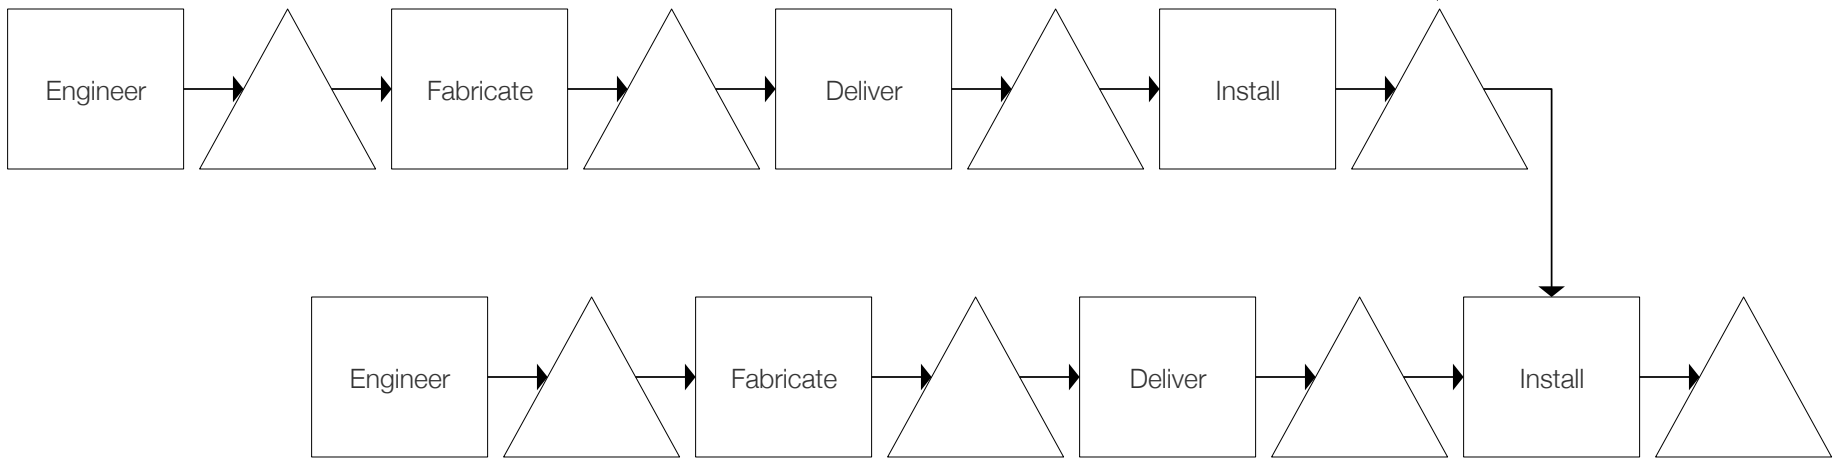

Inventory to optimize use of capacity onsite

□ Operation      → Flow      △ Inventory

WIP (inventory) and/or time to decouple operations between trades or crews enabling optimization of capacity onsite

STOCK is where supply and demand meet

QUEUE is where a part waits for a resource

Faster = More \$

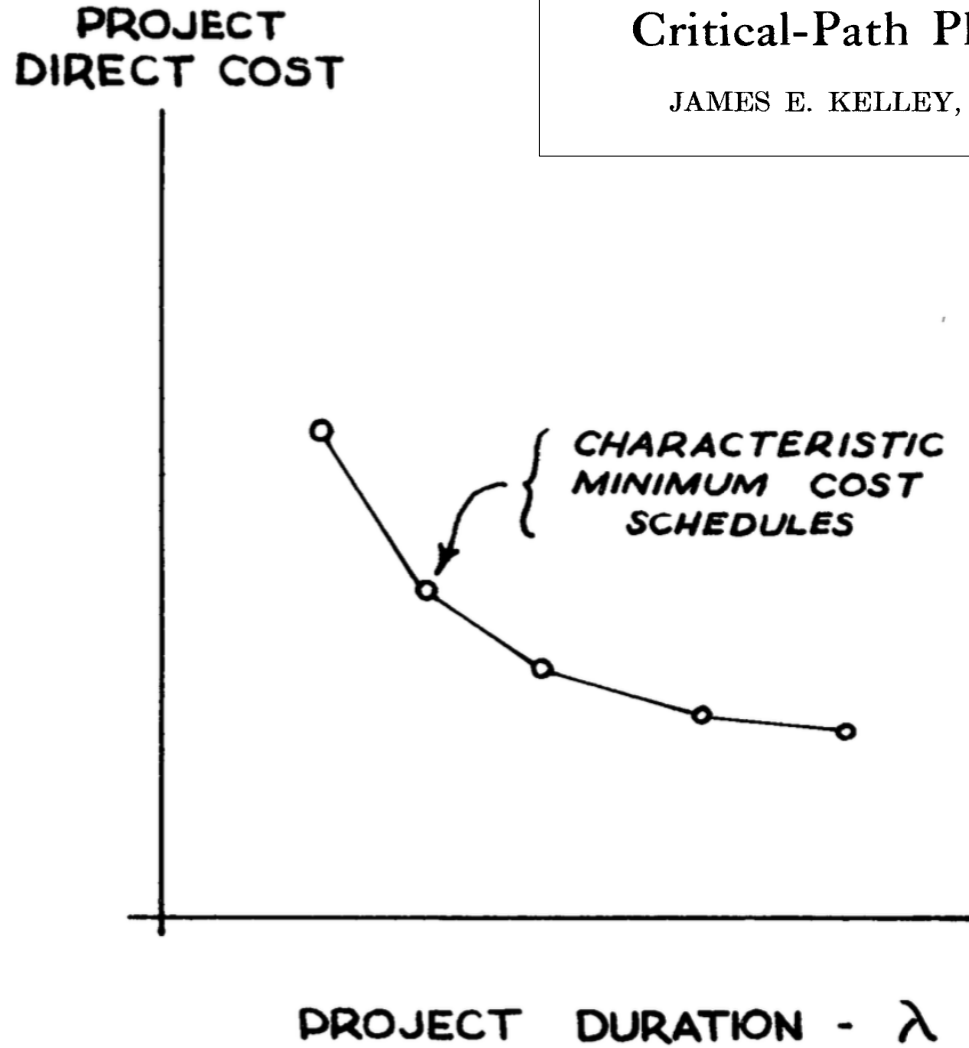

Lower \$ = Slower

Any other solution?

# Critical-Path Planning and Scheduling

JAMES E. KELLEY, JR.† AND MORGAN R. WALKER†

# No variability

# When will it finish?

# Most likely finish time

# Most likely finish time

# What does Early Time cost?

Work in process (WIP)

Little's Law

- $WIP = \text{Early Time} \times \text{Throughput}$
- *Throughput is rate of construction*

So what?

- WIP is money (reduces cash flow)
- WIP can be lost, damaged, or stolen
- WIP can become obsolete when design changes are made

# What does Early Time cost?

Example: Build 1 assembly per day at  
\$100,000 each

Deliver 2 weeks early

\$1.4 million in WIP!

Not counting loss, damage, or obsolete costs

# Where does the Variability come from?

Re-sequencing

New technology

Material defects

New techniques

Material delays

Equipment failures

Longer completion times

Weather delays

Ground conditions

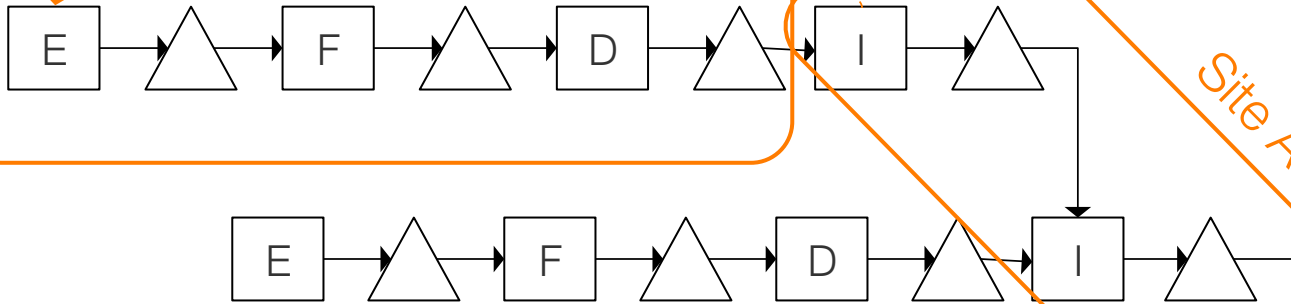

Expedited permits

More favorable locations

Rework

## Supply Flow

What are the effects on variability on a complex project?

# How does Variability effect Wait Time?

Variability behaves like an “incompressible fluid”  
It must go somewhere!

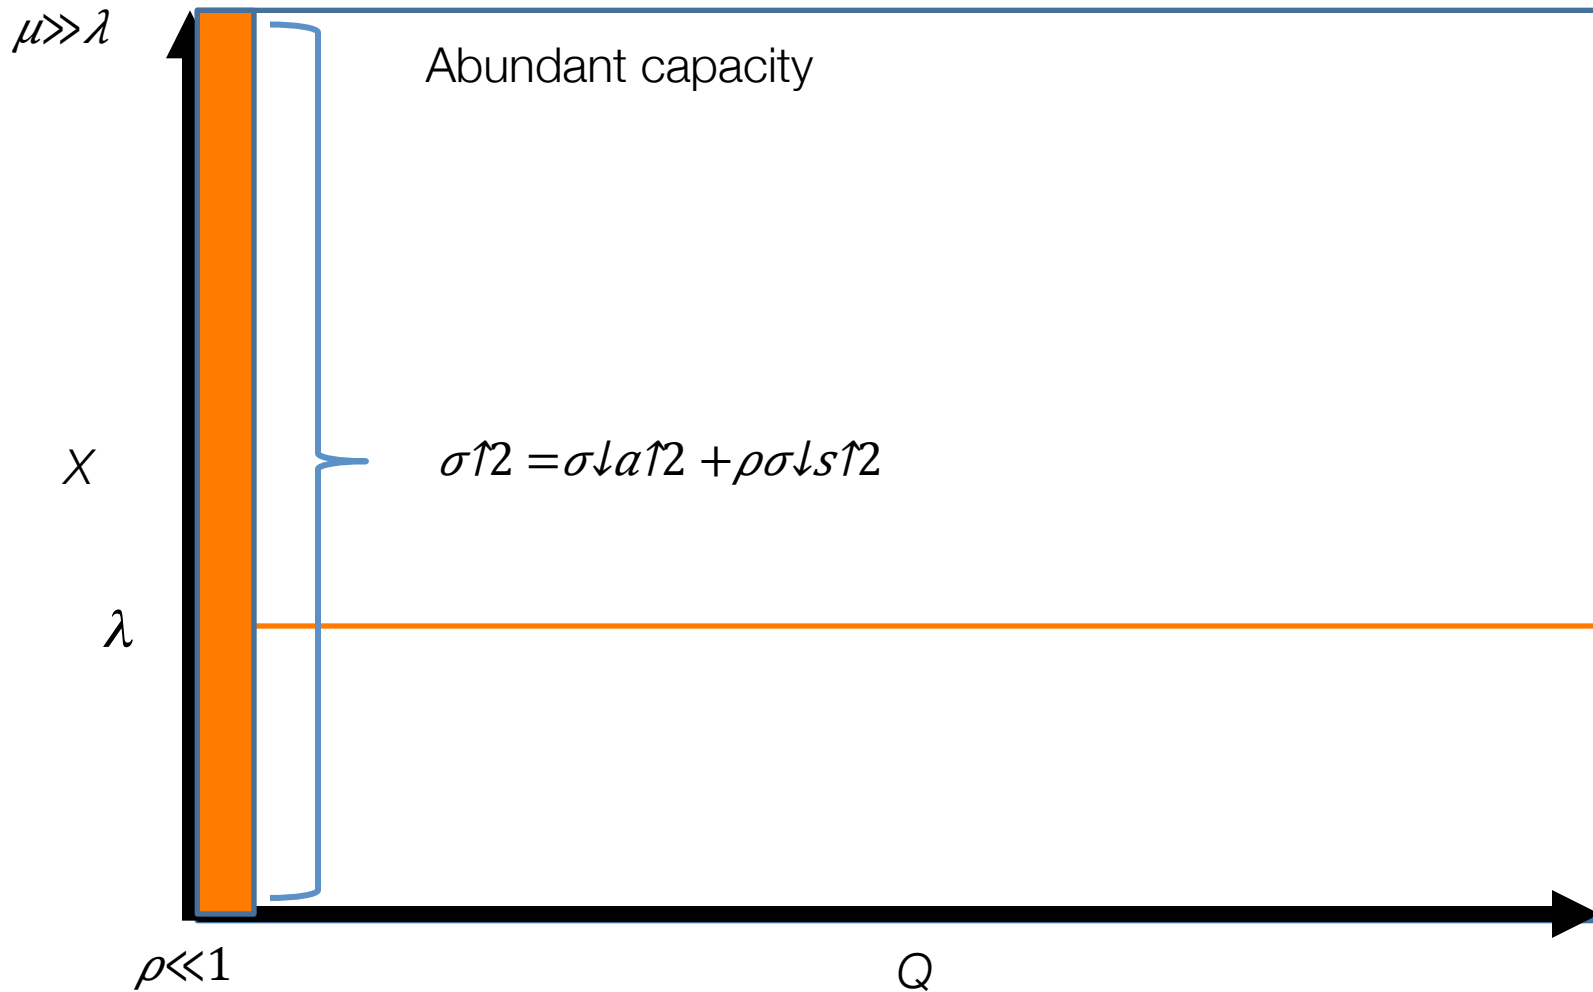

$D(0)$

$t > 0$

$D(t)$

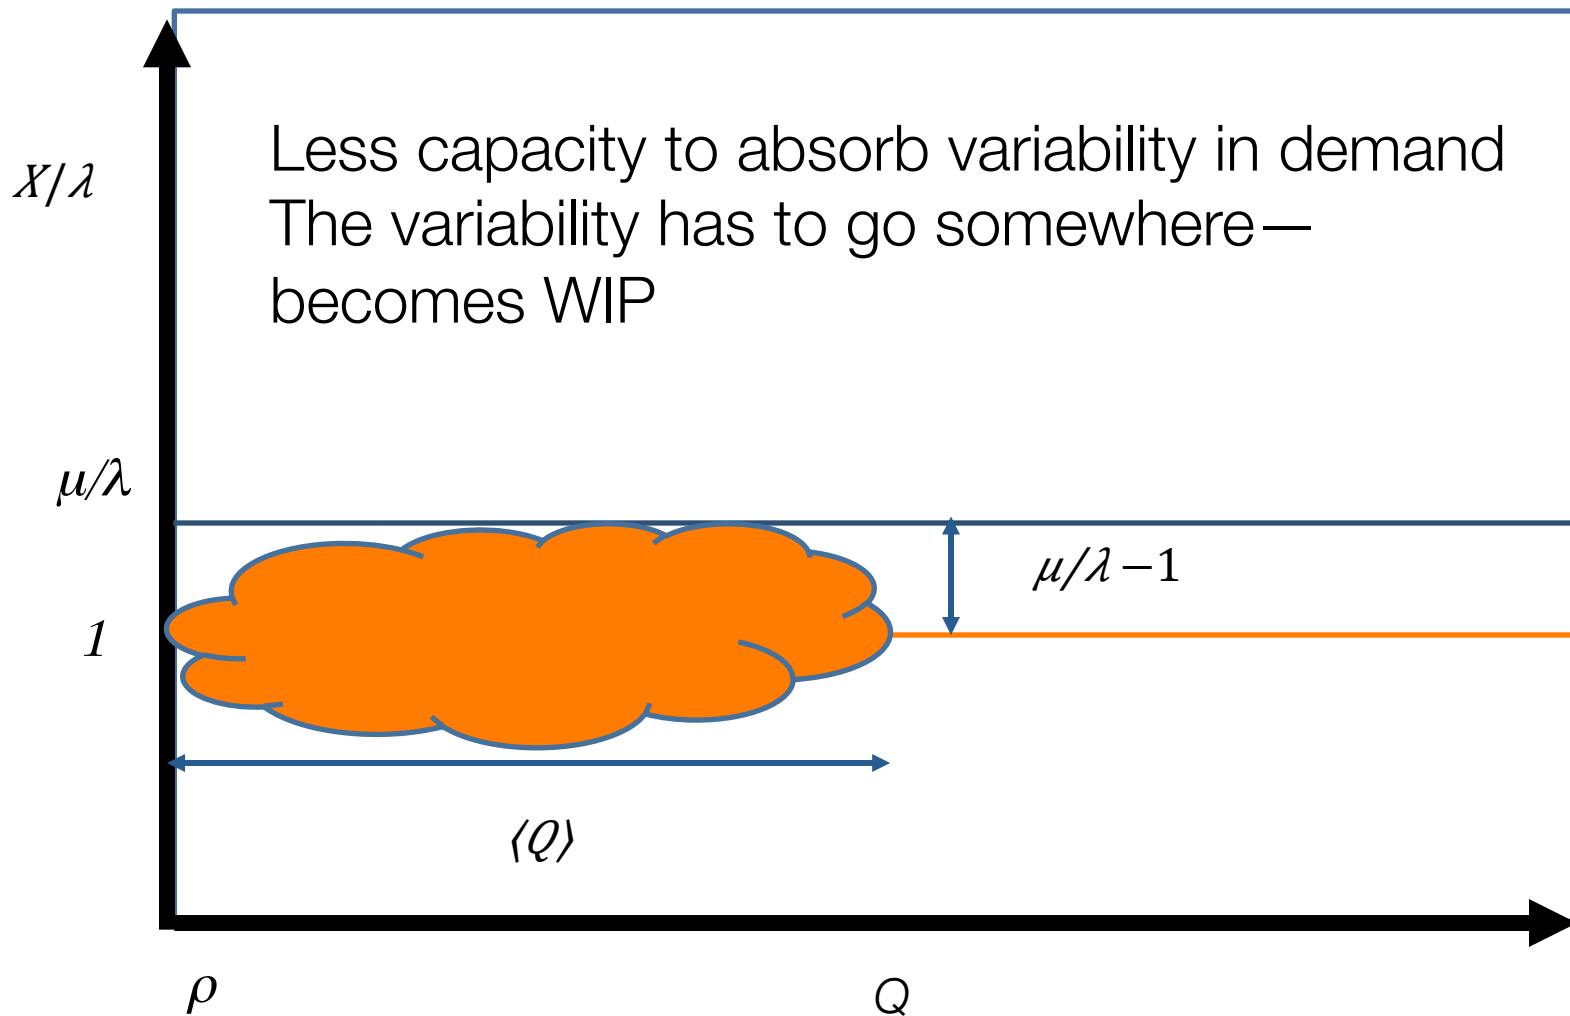

# Variability and Waiting

Number “waiting” is the % of time the resource is busy

# Variability and Waiting

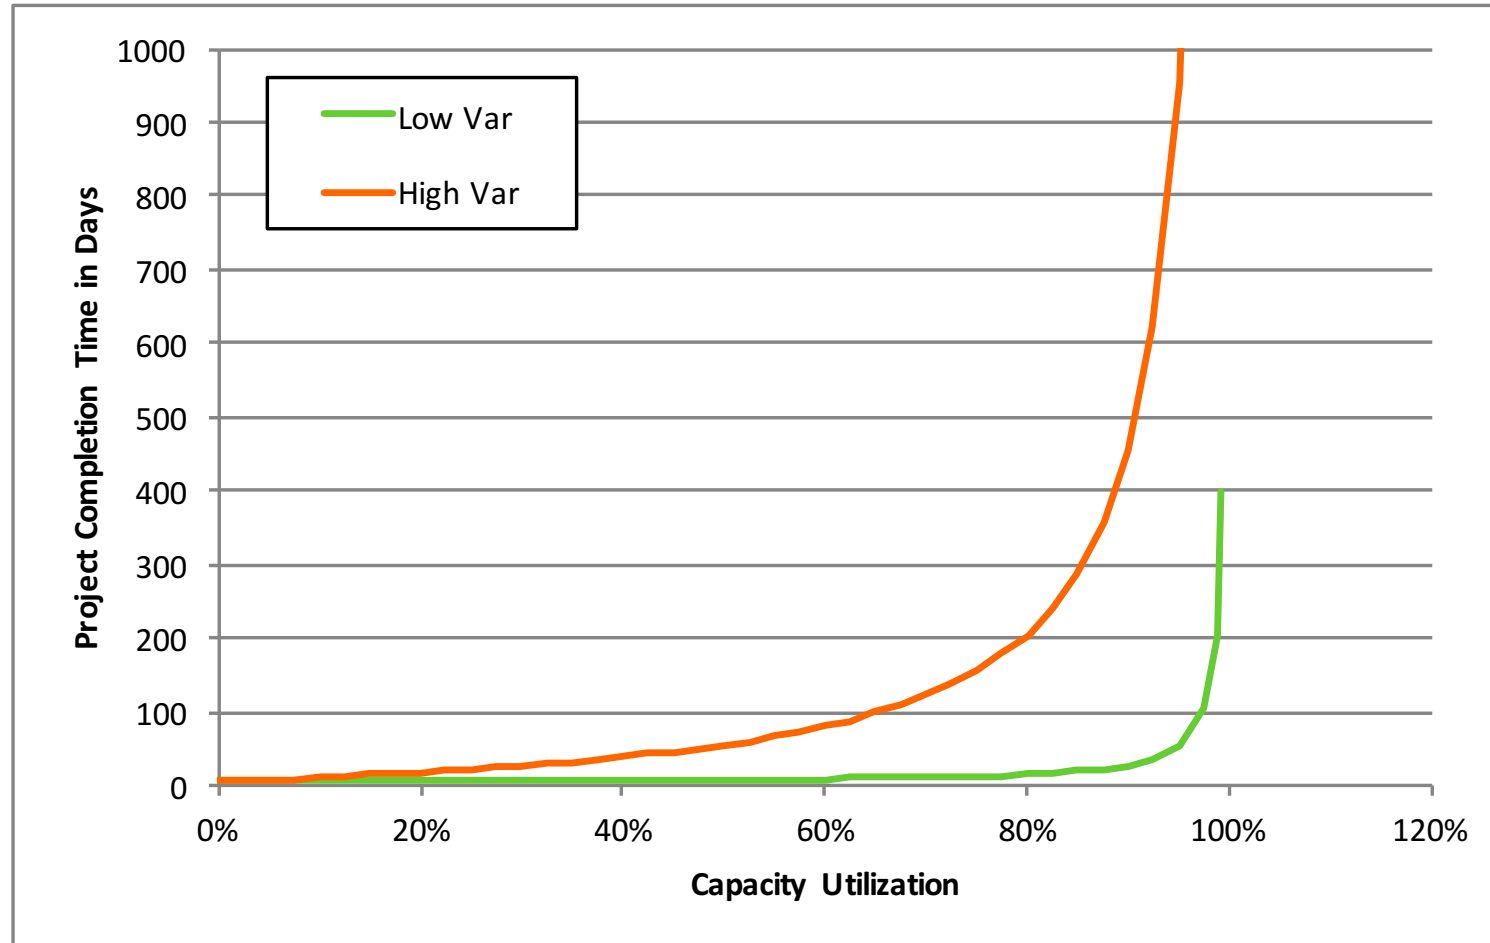

From these two graphs and a little algebra we get the VUT equation

$$\begin{aligned}CT_q &\approx V \times U \times t \\ &\approx \left( \frac{c_a^2 + c_e^2}{2} \right) \left( \frac{u}{1-u} \right)^{t_e}\end{aligned}$$

# Time vs Utilization

# Utilization is related to Cost

Scope: 200,000 Man-Hours

Duration: 1000 Days at 10 hr/day

Rate: \$50 / hr

## Utilization

100%: 200 people required → \$10M

80%: 250 people required → \$12.5M

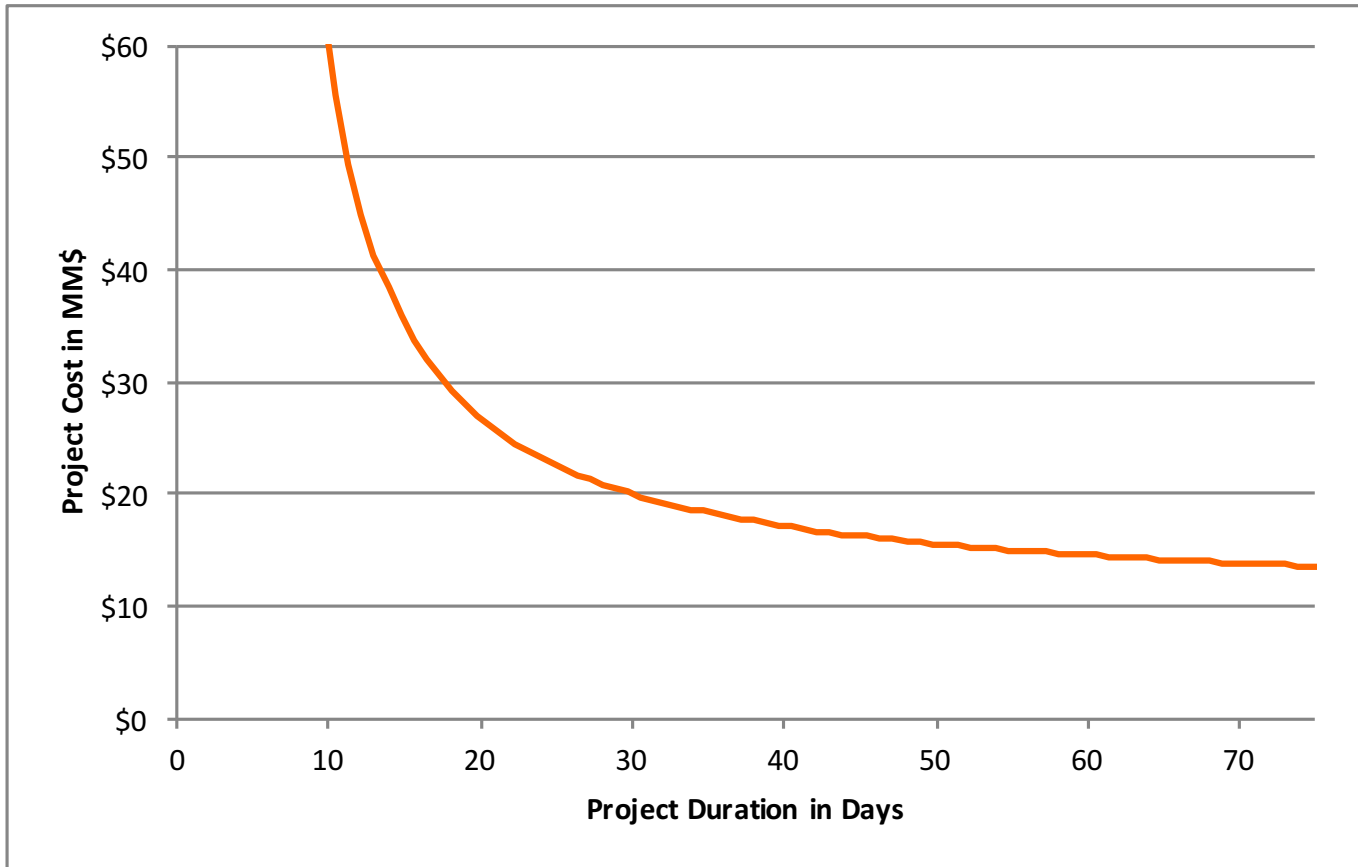

Cost is 25% more!

Is there an implicit amount of variability in our time-cost trade-off curve that we take for granted?

At 100% utilization, with high variability, you never hit 50 days!

# What Typically Happens?

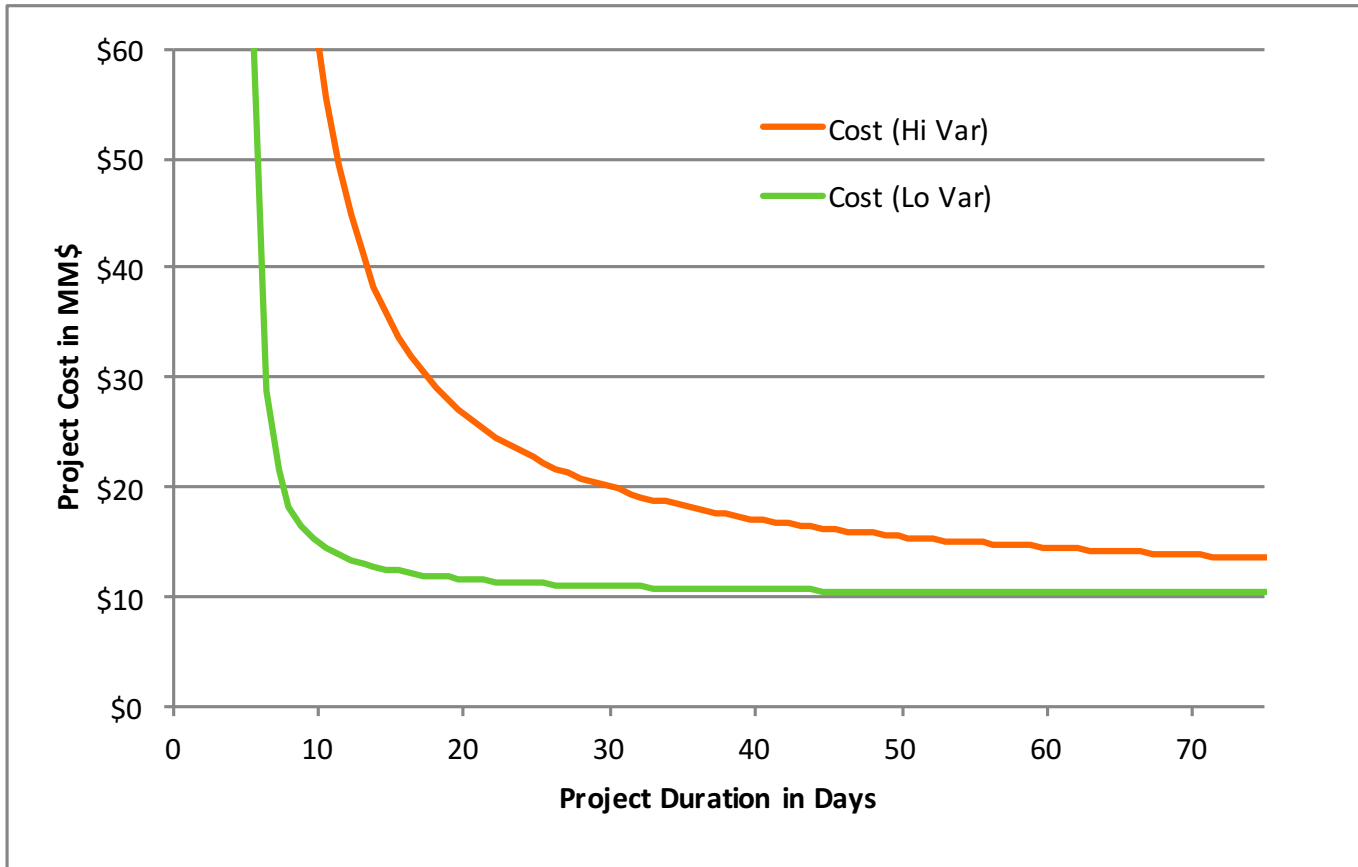

# How Do We Avoid It?

Start even earlier!

With low variability, you are able to achieve 50 days!

Is inventory root of all evil?

Variability is root of evil

Inventory is its flower

How do we make optimal cost –  
inventory/time, variability/complexity  
trade-off decision in a complex  
project production system?

How do we make optimal cost –
